Autoregressive model of order 1 with covariates (AR1C)

Parametrization

This is an extention of the common autoregressive model (AR1) to include a set of covariates into the conditional mean

$$x_1 \sim \mathcal{N}(0, (\tau(1-\rho^2))^{-1})$$

 $x_t = \rho x_{t-1} + \sum_{j=1}^m \beta_j z_{t-1}^{(j)} + \epsilon_t; \qquad \epsilon_i \sim \mathcal{N}(0, \tau^{-1}) \qquad t = 2, \dots, n$

where $|\rho| < 1$. The latent vector has length n + m and is represented as $(x_1, x_2, \dots, x_n, \beta_1, \dots, \beta_m)$.

Hyperparameters

The precision parameter κ is represented as

$$\theta_1 = \log(\kappa)$$

where κ is the marginal precision (when there is no covariates)

$$\kappa = \tau (1 - \rho^2).$$

The parameter ρ is represented as

$$\theta_2 = \log\left(\frac{1+\rho}{1-\rho}\right)$$

and the prior is defined on $\theta = (\theta_1, \theta_2)$.

Specification

The AR1C model is specified as

```
f(<whatever>, model="ar1c", hyper = <hyper>,
  args.ar1c = list(Z=Z, Q.beta = Q))
```

The covariates are given in the **matrix** Z and **must have** dimension $n \times m^1$. The prior for $\beta = (\beta_1, \ldots, \beta_m)$ is a zero mean Gaussian with a $m \times m$ precision **matrix** \mathbb{Q} .
