Gaussian model for Stochastic volatility

Parametrization

The Gaussian likelihood for stochastic volatility models is defined as:

$$y|\ldots = \sigma\epsilon$$

where

$$\epsilon \sim \mathcal{N}(0,1)$$

Link-function

The squared of the scale parameter σ is linked to the linear predictor η as:

$$\sigma^2 = \exp(\eta) + 1/\tau$$

where $1/\tau$ is an possible offset in the variance.

Hyperparameters

This likelihood has one hyperparmeter

$$\theta = \log(\tau)$$

and the prior is defined on θ .

See Notes for more info about the possible offset in the variance, as default $1/\tau = 0$ and fixed.

Specification

- family="stochvol"
- \bullet Required argument: y.

Example

In the following example we specify the likelihood for the stochastic volatility model to be Gaussian

Notes

The default setting treat θ as fixed and with an initial value so that $1/\tau = 0$. If θ is random, then you must also give it a reasonable initial value.
