# The Berkson Measurement Error (MEB) model

#### Parametrization

This is an implementation of the Berksom measurement error model for a fixed effect. The observed covariate is w but it is x that goes into the linear predictor

$$\eta = \ldots + \beta x + \ldots$$

where x = w + u. The error term u is Gaussian with prior  $\mathcal{N}(0, \tau_u \mathbf{D})^1$ , where  $\tau_u$  is the observational precision of the error  $\operatorname{Prec}(u|x)$ ) with possible heteroscedasticy, encoded in the entries  $d_i$  of the diagonal matrix  $\mathbf{D}$ . The vector s contains the fixed scalings  $s = (d_1, \ldots, d_n)$  (with n the number of data points).

#### Hyperparameters

This model has 2 hyperparameters,  $\theta = (\theta_1, \theta_2)$ . The hyperparameter specification is as follows:

$$\theta_1 = \beta$$

and the prior is defined on  $\theta_1$ ,

$$\theta_2 = \log(\tau_u)$$

and the prior is defined on  $\theta_2$ .

#### Specification

The MEB is specified inside the f() function as

```
f(w, [<weights>,] model="meb", scale = <s>, values= <w>, hyper = <hyper>)
```

Here, w are the observed covariates, and the fixed scaling of the observational precision is given in argument scale. If the argument scale is not given, then s is set to 1.

Note that only the unique values of w are used, so if two or more elements of w are *identical*, then they refer to the *same* element in the covariate x. If data points with identical w values belong to different x values (e.g., different individuals), please add a *tiny* random value to w to make this difference obvious to the model.

#### Hyperparameter specification and default values

Example
n = 100
beta = 2
w = rnorm(n)
prec.u = 1
prec.y = 1
## heteroscedastic scaling
s = runif(n,min=0,max=1)
## true but unobserved covariate
x = w + rnorm(n, sd = 1/sqrt(s*prec.u))
y = 1 + beta*x + rnorm(n, sd = 1/sqrt(prec.y))
## prior parameters
prior.beta = c(0, 0.0001)
prior.prec.u = c(10, 9/prec.u)
prior.prec.y = c(10, 9/prec.y)
formula = y ~ f(w, model="meb", scale=s, values=w,
    hyper = list(
        beta = list(
            prior = "gaussian",
```

```
param = prior.beta,
            fixed = FALSE
        ),
        prec.u = list(
            prior = "loggamma",
            param = prior.prec.u,
            initial = log(prec.u),
            fixed = FALSE
        )
   )
)
r = inla(formula, data = data.frame(y, w, s),
    family = "gaussian",
    control.family = list(
        hyper = list(
            prec = list(param = prior.prec.y,
                fixed = FALSE
            )
        )
   )
)
```

#### Notes

- INLA provides the posteriors of  $\nu_i = \beta x_i$  and NOT  $x_i$ .
- The posteriors of  $\nu_i$  come (default) in the order given by the sorted (from low to high) values of w. The entry \$ID gives the mapping.
- The option scale defines the scaling in the same order as argument values. It is therefore adviced to also give argument values when scale is used to be sure that they are consistent.
